

Access Layer and Aggregation Layer of Switches

Overview

The aggregation or distribution switches are the intermediary layer between the core and access layers. The lowest tier is the access layer, which is used to connect all of the various end devices, such as PCs, printers, and other network components such as routers or access. Knowing the roles of core, aggregation, and access switches in contemporary network topology becomes essential to create effective and scalable networks. This article looks at what each such tool does, compares how they differ from each other, and offers suggestions as to what sort of network each. If a campus network is part of an enterprise network, it allows end users and devices to access network services and resources within the same geographic area or in proximity. The Cisco three-layer hierarchical model provides recommendations for designing campus LANs. Together, these layers can offer consumers a network that is safe, reliable, and affordable.
