

Transmission Network Optical Layer Technology

Overview

OTN transmission technology is a technology that realizes functions such as service signal transmission, multiplexing, and routing in the optical domain. This technology complies with the general model of transmission network specified in ITU-T6. Key elements of OTN include: Standardized framing (the “digital wrapper”): OTN adds overhead. An optical transport network (OTN) is a digital wrapper that encapsulates frames of data, to allow multiple data sources to be sent on the same channel. ITU-T defines an optical transport network as a set of optical network. Each layer plays a crucial role in optimizing network performance, with the access layer focusing on user connectivity, the aggregation layer on efficient data consolidation, and the core layer on robust and high-capacity interconnectivity. Figure 1: Optical Network Hierarchy Diagram The Access. OTN—or Optical Transport Network—is a telecommunications industry standard protocol— defined in various ITU Recommendations, such as G. 798—that provides an efficient way to transport, switch, and multiplex different services onto high-capacity wavelengths across the optical network.

Optical Transport Network

An optical transmission system is a part of the transport layer in a service provider's network. The transmission system carries information on optical channels, which have certain protocols, such as

Optical transport network

An optical transport network (OTN) is a digital wrapper that encapsulates frames of data, to allow multiple data sources to be sent on the same channel. This creates an optical virtual private network for each client signal. ITU-T defines an optical transport network as a set of optical network elements (ONE) connected by optical fiber links, able to provide functionality of transport, multiplexing
